Study Area

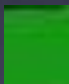

Monitoring of 10 Experimental watersheds

Stand Age: 11 years
 Mean Height (m): 20.4
 dbh (cm): 16.5
 Stand Density: 1533
 trees/ha
 Basal Area (m^2/ha): 37
 Standing Vol: (m^3/ha): 288

 To be harvested (44.5 ha)
 Areas within watersheds
 Riparian strips

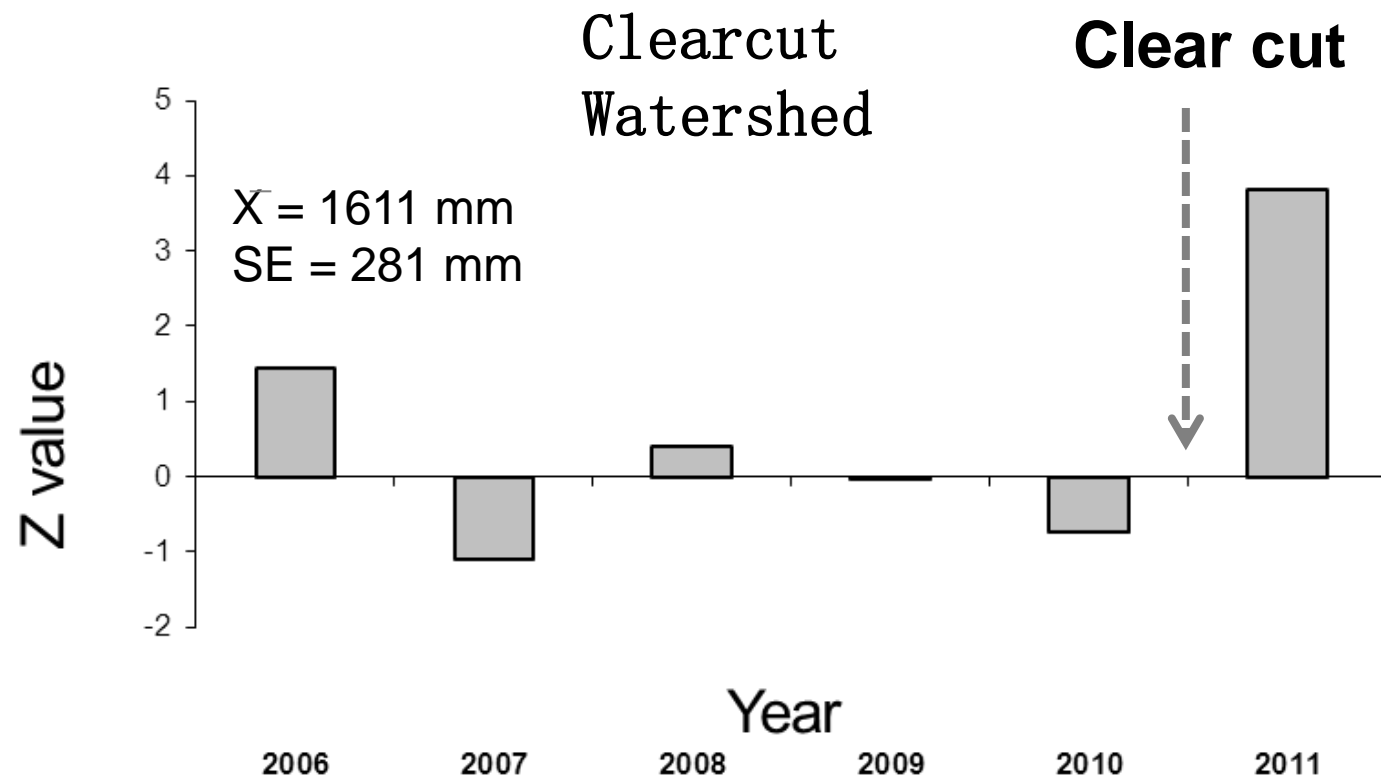

- Clear Cut of Eucalypt plantations February – March 2011–2012 (45 ha)
- Plantation with *Nothofagus dombeyi* (1300 seedlings per ha) plus natural regeneration

Runoff Coefficients (Runoff/precipitation)

Annual trends

Challenging Future Scenario

- Need to continue producing timber and water
- Increase in the demand for water
- Increase in social valuation of water and other ecosystem services
- Climatic change and land use change
 - Decrease in precipitation
 - Increase in temperature
 - Rapid expansion of forest plantations and agriculture

Regional Problems addressed

- 1) Scarcity and variability of water resources in Central and Southern Chile.
- 2) Rapid land use changes in Central and Southern Chile.

Objectives as stated in Proposal

Objective 1

Design of landscapes for the combined production of diverse Ecosystem Services

- To analyze and design landscape configurations with different proportions of the various land-use categories and their location that provide a

combined production of market goods and ecosystem services in the watershed (e.g., timber and water provision or multifunctional landscapes) and that are more resilient to changes in the demand, vulnerability and provision of ecosystem services.

Objective 2

To investigate the recovery of ecosystem services from ecological restoration under a global ecology approach

- To evaluate the ecological and bio-physical processes that determine the dynamics, resilience, recovery and the restoration potential of water provision as an ecosystem service of forested watersheds.
- To assess the structural and organizational response of the benthic macro-invertebrates community to the variability of streams-flow regimes associated with native forest and exotic plantations watersheds, as a basis for the restoration of freshwater ecosystems.

Objective 3

To assess the potential of ecological restoration for building resilience, adaptation and mitigation to climate change.

- To evaluate the potential effectiveness of ecological restoration to develop adaptation to climate change to increase water provision and other ecosystem services at various spatial and temporal scales, considering different climate and land use change scenarios.

Objective 1 Design of landscapes for the combined production of diverse Ecosystem Services

Purapel (25.000 ha) and Cauquenenes (70.000 ha) watersheds

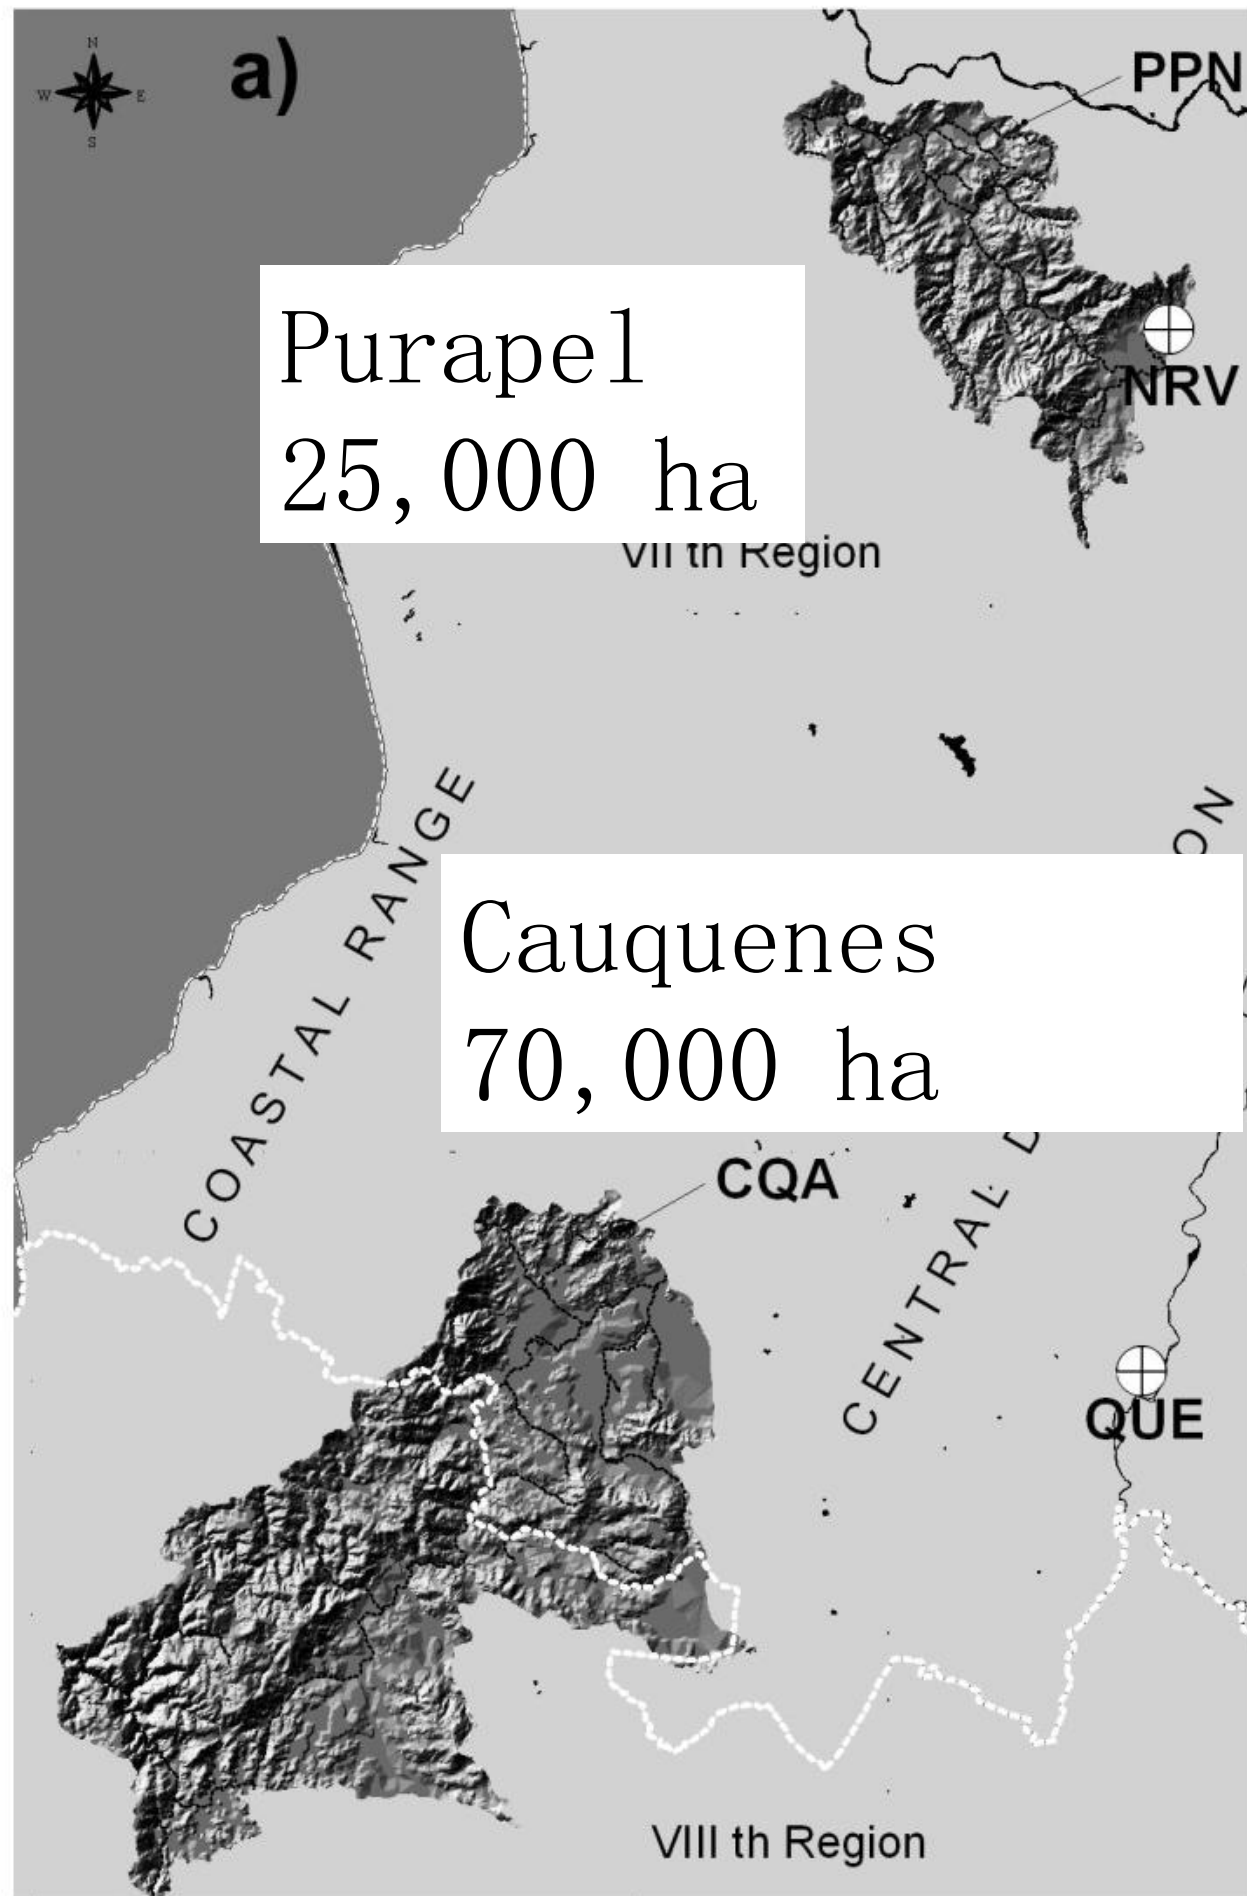

Task 1: Compilation of land use GIS databases and updating of satellite imagery.

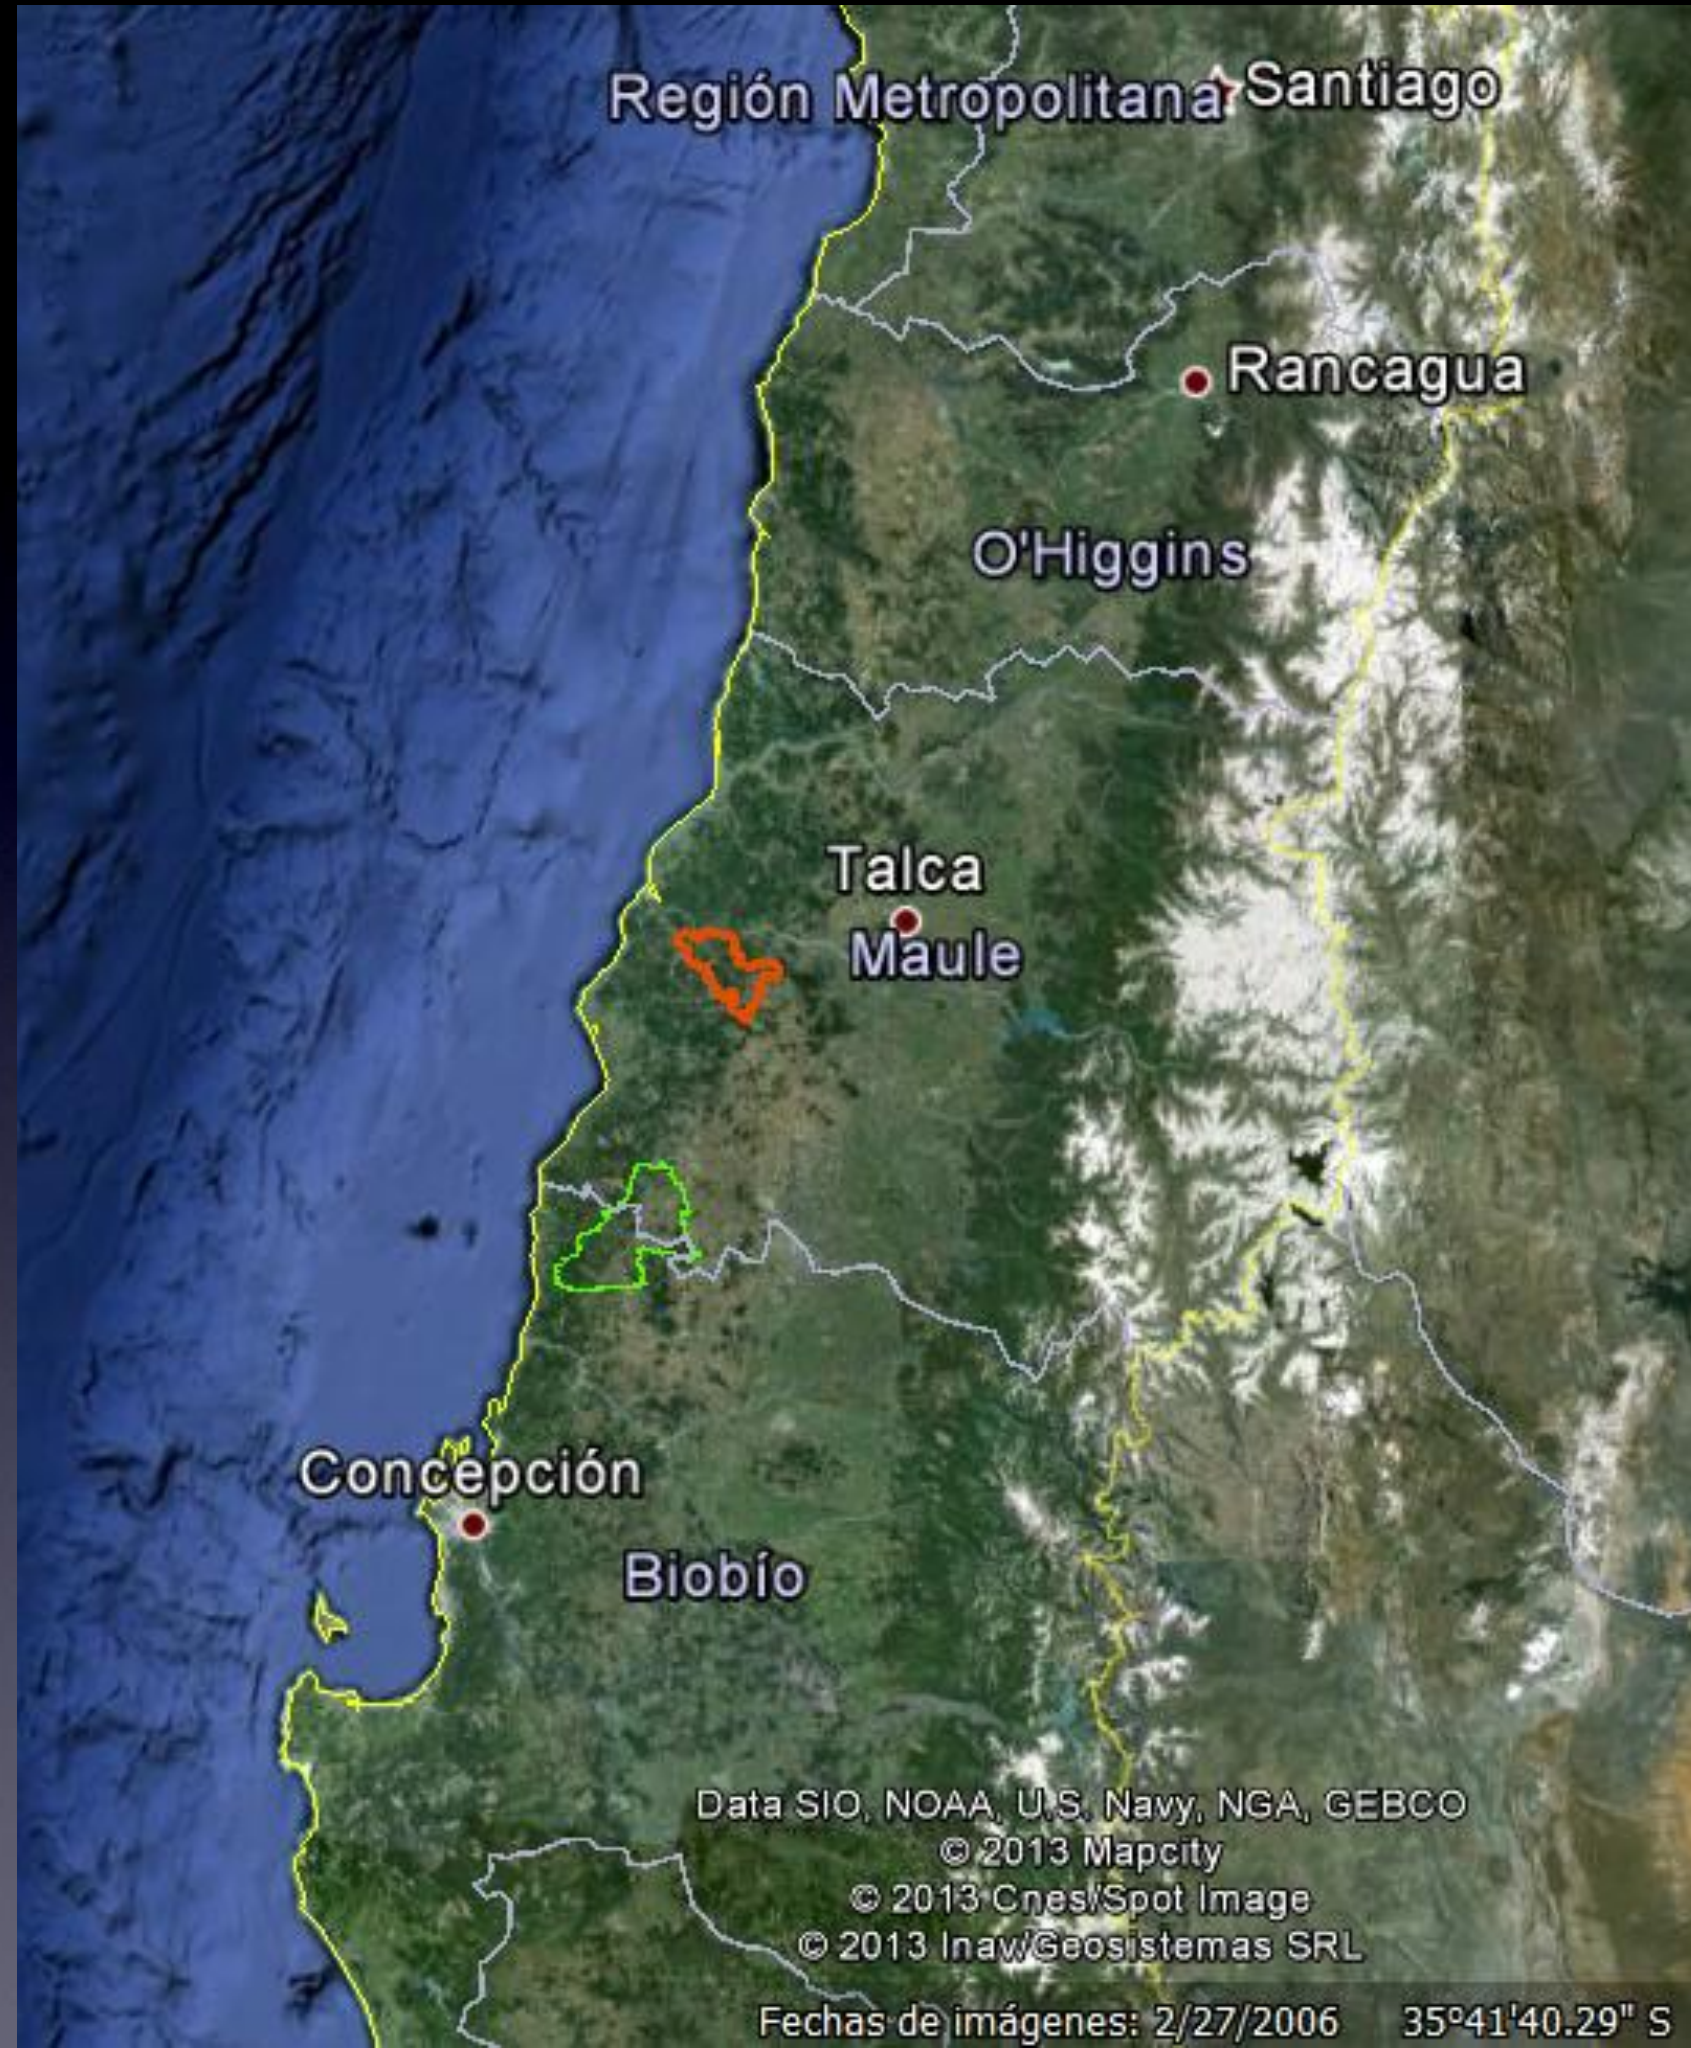

Task 2. Compilation of water rights allocated in the watersheds, their location and time series of their allocation on the watersheds.

Task 3. Description of the processes and drivers of land use change through logistic regression analysis (e.g. kind of land owners, distance to industries, distance to roads, etc).

Task 4. Establishment of the statistical relationships between land use change and streamflow trends.

Task 5. Simulations to generate landscape configurations to provide better solutions for a combined provision of multiple ecosystem services, considering various land use changes and climate changes.

Objective 2 To investigate the recovery of ecosystem services from ecological restoration under a global ecology approach

Reserva Costera Valdiviana (10 watersheds 1 – 175 ha)

Other Study areas (Maule – Los Lagos Regions)

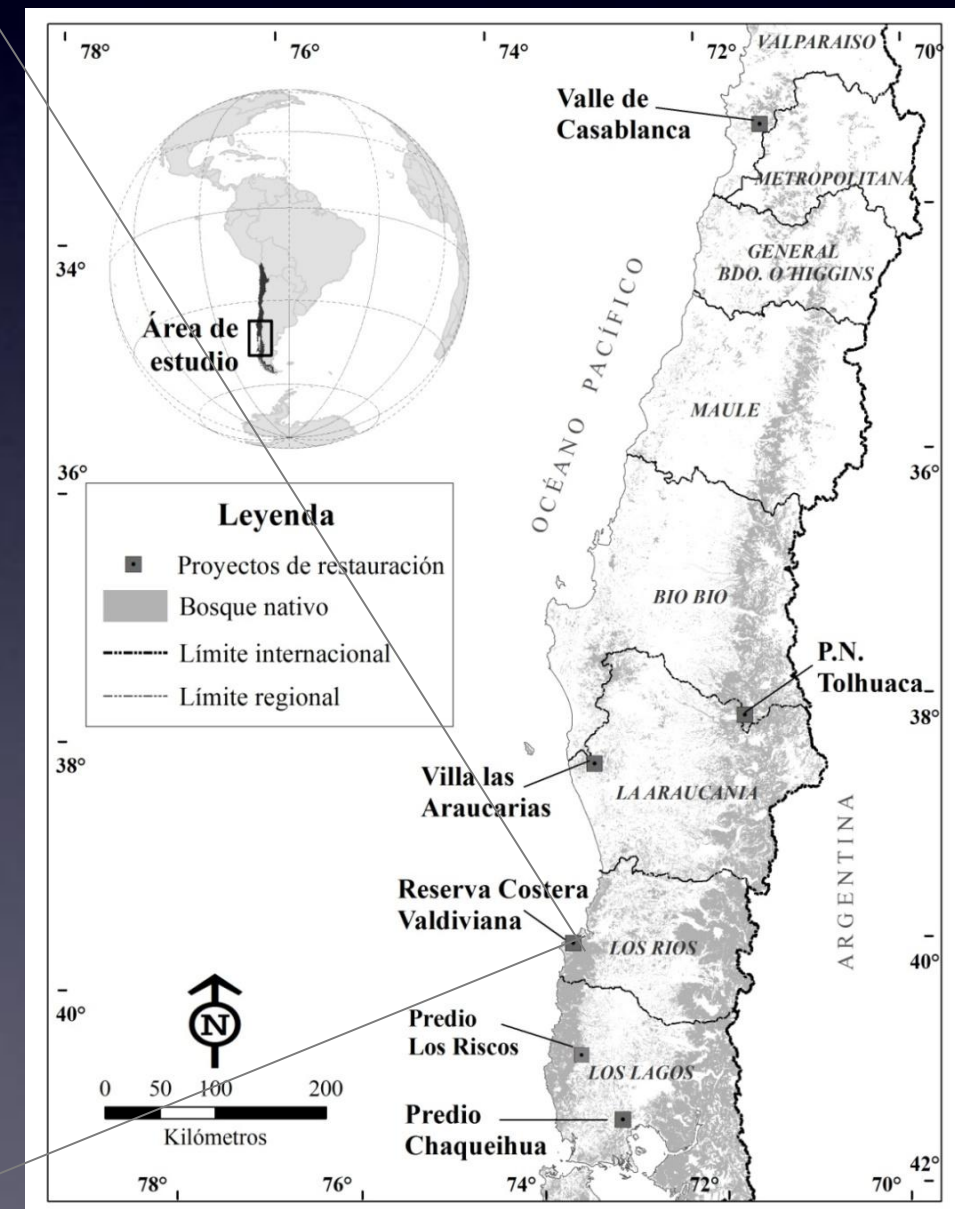

Task 1: Measure and monitor the regeneration, productivity, carbon balance, resilience and other functional traits of different native forest types, site conditions and disturbances.

Task 2: Collect field data and monitor permanent plots from areas disturbed by natural and human to assess their natural recovery in different study areas .

Task 4: Monitor of streamflow and water quality of experimental watersheds located in the Valdivian Coastal Reserve (VCR).

Task 5: Conduct studies on ecosystem resilience after disturbances with forests located in other temperate regions, developing indices and protocols.

Study Area

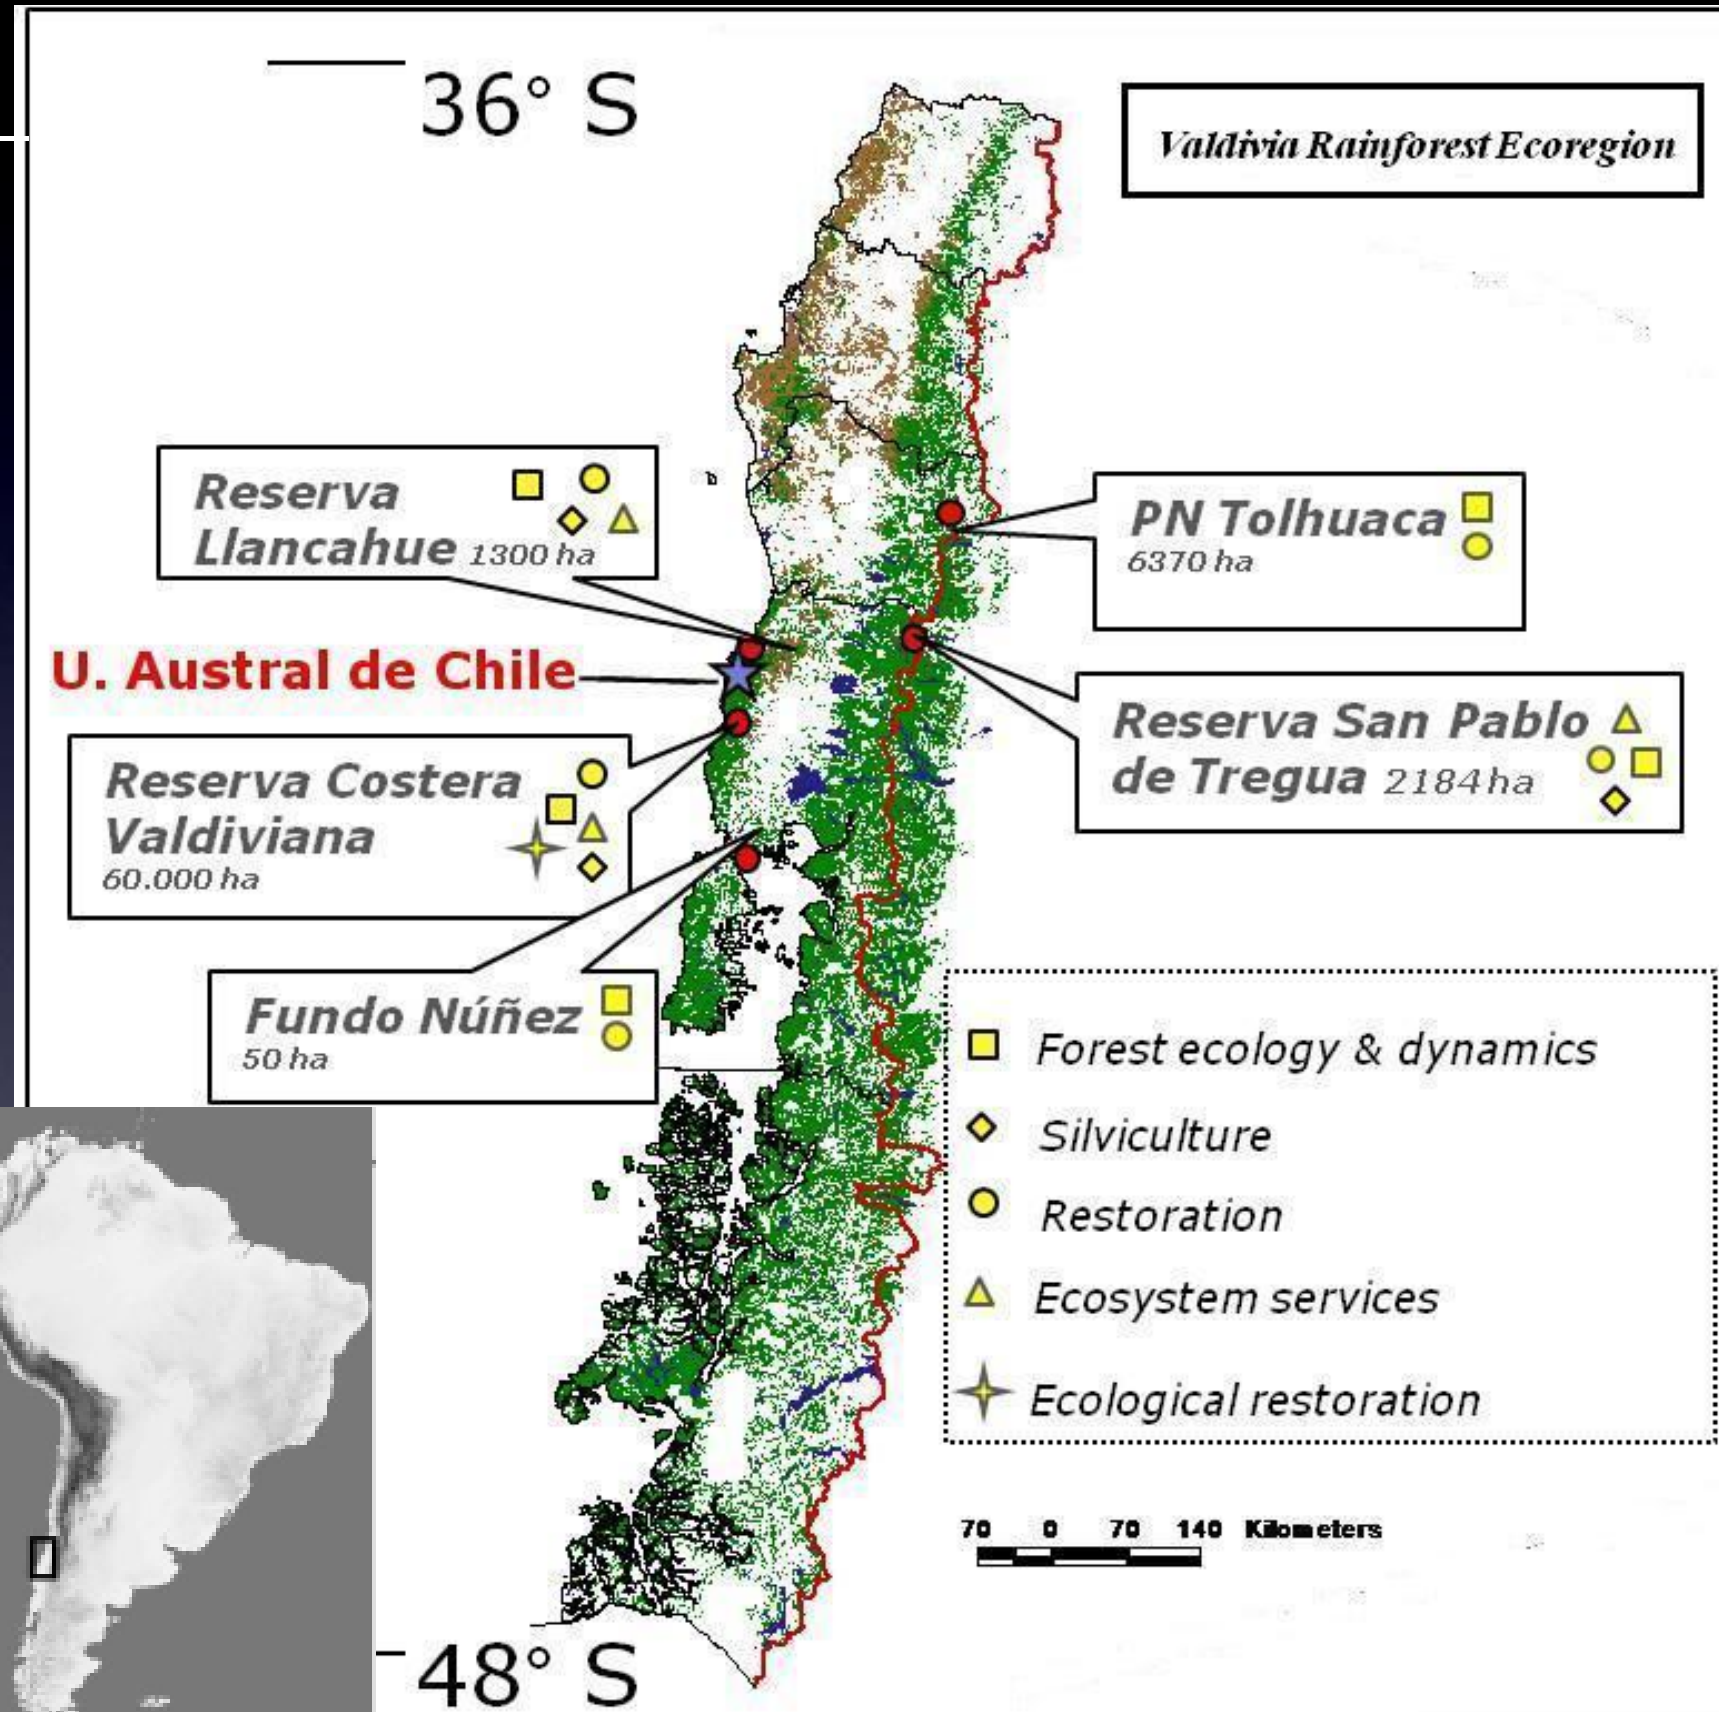

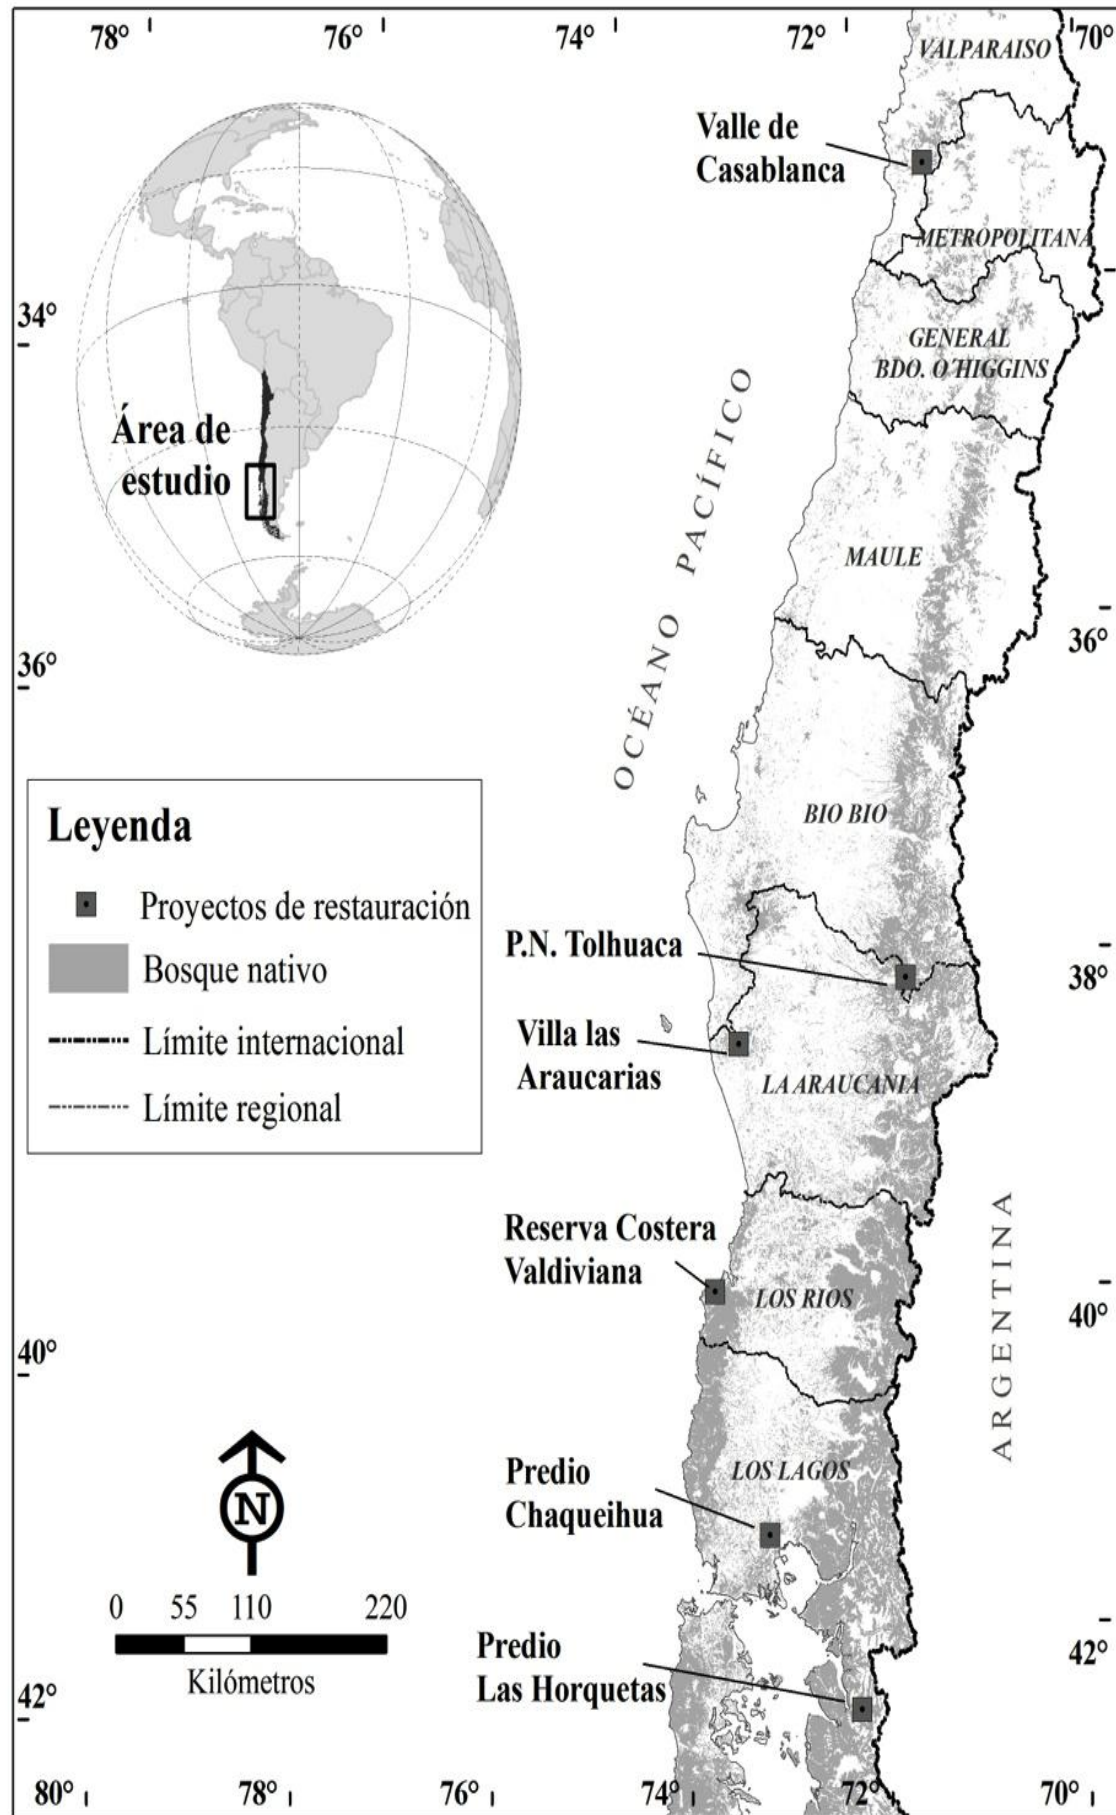

Long Term Ecosystem Study Sites

Valdivian Rainforest Ecoregion

Among Those Highest Conservation Priority Worldwide
WWF – WB

- Endemisms
- Threats

- 6 Proyectos de Restauración
- Iniciados desde 1998
- Más de 230 ha
- Involucran a actores muy diferentes: Academia, ONGs internacionales, fundaciones, empresas,

Representación de las cuatro fases del ciclo adaptativo para dos propiedades del ecosistema: potencial de crecimiento y conectividad (Holling 2001).

α : iniciación de la sucesión; r : bosque en pleno crecimiento κ : bosques avanzados; Ω : disturbio.

Effective Restoration

From M. A. Palmer et al. 2005

Objective 2 To investigate the recovery of ecosystem services from ecological restoration under a global ecology approach Study areas

Gradient of small selected watersheds in Reserva Costera Valdiviana, other in Araucanía, Bío-Bío nested watersheds within Purapel and Cauquenes and other (100 – 5,000 ha)

Task 1: To select the watersheds and streams for sampling the whole benthic invertebrate community on a seasonal basis. with different magnitude of disturbance (pristine native forest, old forest plantations, young plantations and recent clear-cuts).

Task 2 : To determine the taxonomic composition, size distribution, and total abundance of the benthic invertebrate community from watersheds with different disturbance and disturbance history.

Task 3: To develop an index of benthic invertebrate community

Objective 3 To assess the potential of ecological restoration as a mean for building resilience, adaptation and mitigation to climate change

Study areas

Maule to Los Lagos Regions (35° – 43° S)

Task 1: To assess the potential increase in water provision derived from ecological restoration for selected watersheds and upscale these estimates to larger watersheds and regions.

Task 2. Analysis of other restoration activities and derived increase in the provision of ecosystem services with potential to contribute to the resilience and adaptation to climate.

Task 3. Estimation of the rates and magnitude of increase of the selected ecosystem services in different space and time scales and their comparison with the expected reductions of these services predicted by climatic change and land use change.

Task 5. Economic evaluation of the costs and benefits of the proposed restoration activities compared to alternative measures for the

Development of the science for decision making

1 need of a large scale restoration plan for native forests in South-central Chile.

- Design of balanced landscapes with an adequate proportion of forest plantations and native forests for the compatible production of timber and water (quantity and quality).

2. Restoration of native forests to increase water supply should be a top priority within the National Strategy for the Adaptation to Climatic Change in Chile.

- Significant increase in public and private investment.
- Modifications to current Forest Laws to introduce subsidies for the maintenance and recovery of water provision
